

ABSTRACT OF THE DISCLOSURE

A method for evaluating the quality of abrasive grains for polishing glass, which comprises adding abrasive grains to be measured, to an aqueous medium  
5 having silica dissolved therein, to have the silica adsorbed on the abrasive grains under such a condition that the silica undergoes substantially no polymerization in the aqueous medium, followed by solid-liquid separation to separate the abrasive grains from the  
10 mother liquor, and measuring the concentration of silica remaining in the mother liquor to measure the adsorption rate ( $\eta$ ) of silica on the abrasive grains.
